Wearing elastic compression stockings during long-haul flights prevented the development of deep venous thrombosis

QUESTION: In passengers on long-haul flights, does wearing class-I elastic compression stockings while flying prevent the development of deep venous thrombosis (DVT)?

Design
Randomised (unclear allocation concealment*), blinded (outcome assessor),* controlled trial with 48 hours of follow up.

Setting
Stamford Hospital, London, UK.

Patients
231 people who were 56 to 68 years of age (mean age 62 y, 61% women) and who intended to travel economy class with 2 sectors of ≥ 8 hours’ duration within 6 weeks of enrollment (median flying time 24 h [interquartile range 19 to 35 h] for stocking group, 22 h [interquartile range 18 to 36 h] for control group). Exclusion criteria were episodes of venous thrombosis, use of anticoagulants, regular use of compression stockings, cardiorespiratory problems, or any other serious illness. 87% of people completed the study and were included in the analysis.

Intervention
People were allocated to class-I (German Hohenstein compression standard; 20 to 30 mm Hg) below-knee elastic compression stockings (n = 115) or no stockings (n = 116). People were advised to put on the stockings before departure and to remove the stockings after arrival for every flight they took.

Main outcome measure
Presence of DVT confirmed by duplex ultrasonography.

Main results
Analysis was by intention to treat. At 48 hours after flight travel, no people in the stocking group had symptomless DVT, whereas 12 people in the control group did (p < 0.001)† (table). 4 people in the stocking group had superficial thrombophlebitis, whereas no people in the control group did (p = 0.04)† (table).

Conclusion
In passengers on long-haul flights, wearing class-I elastic compression stockings while flying prevented the development of symptomless deep venous thrombosis but increased the risk for superficial thrombophlebitis.

COMMENTARY
For years, it has been assumed that taking long aeroplane trips were associated with an increased risk for DVT—the so-called economy class syndrome. However, despite this assumption, few hard data exist to quantify the risk. One surprising finding in the study by Scurr et al was the high incidence of asymptomatic thrombosis in the control group: 10%. Given the decreased sensitivity of ultrasonography for calf vein thrombosis, this finding may be an underestimate. This rate of thrombosis approaches that for general surgery patients. However, all the thrombi were asymptomatic calf vein thrombosis, and it is still unknown if more travellers were screened if an increase in the incidence of proximal vein thrombosis would be found. Also unknown is whether thrombosis rates would be higher in at-risk patients who were excluded from the study.

The cause of the thrombi is probably venous stasis that results from prolonged sitting. It has been known since World War II that sitting can predispose individuals to thrombosis. Although the hypoxic cabin environment is often touted as a cause of thrombosis, recent data suggest that this is not the case, and, in fact, hypoxia may actually increase fibrinolysis.

Elastic stockings are known to offer modest DVT protection in surgery patients. Stockings were effective and are an easily applied prophylactic measure, especially given the difficulties in trying to exercise in modern aircraft. It is still unknown whether patients at higher risk for thrombosis would benefit from more aggressive pharmacological prophylaxis.
