Review: antidepressants improve headache in patients with chronic headache

QUESTION: In patients with chronic headache, how effective are antidepressants?

Data sources
Studies were identified by searching Medline (1966 to December 1998), PsycLIT (1974 to December 1998), EMBASE/Excerpta Medica (1974 to December 1998), and the Cochrane Library. Bibliographies of relevant articles were reviewed, and Federal Research in Progress was searched for information on unpublished trials.

Study selection
Studies in any language were selected if they were randomised controlled trials (RCTs) comparing the effectiveness of antidepressants with placebo in patients with chronic headache and if measurable outcomes were reported.

Data extraction
Data were extracted on setting, country of origin, patient inclusion and exclusion criteria, sample size, demographical characteristics, comorbid psychiatric disease, concurrent use of analgesic medications, key components of the intervention, study quality, adverse effects, and outcomes. Outcomes were overall improvement in headache (> 50% reduction in Headache Index scores, global improvement based on > 50% improvement, impression of improvement, or headache frequency or severity) and effect size of treatment (measured in standard deviation units) on headache burden.

Main results
38 RCTs met the selection criteria. Interventions included tricyclic antidepressants (TCAs) (19 RCTs), serotonin blocking agents (18 RCTs), and selective serotonin reuptake inhibitors (SSRIs) (7 RCTs). The rate of overall improvement in headache was greater in the treatment group than the placebo group (p < 0.05) (table). Improvement in headache burden (measured by effect size of treatment) was greater in the treatment group than the placebo group (SMD –0.7, CI –0.9 to –0.5). Outcomes did not differ by type of headache (migraine or tension) and drug class (TCAs, serotonin receptor antagonists, or SSRIs), with the possible exception that SSRIs are not as well studied and may be less effective. The effect seems independent of the presence of depression, but studies are inconsistent.

The results of Tomkins et al are consistent with those of other systematic reviews1–2 and indicate that antidepressants, especially TCAs, are a reasonable first choice to treat headaches. The choice of treatment depends on the patient’s comorbid illnesses that might be improved or worsened by the treatment for headache.

The authors’ thorough analysis shows problems in the published studies. First, the authors found statistically significant heterogeneity among the studies with a 4-fold variation in rate ratios. This finding is not surprising given the range of drugs and patients. Second, the authors found statistical evidence of publication bias. Although unpublished studies will probably not reverse the results of this meta-analysis, unpublished negative studies probably lessen the degree of benefit.

Two types of studies are now needed. First, we need larger studies to reduce the effect of publication bias and allow effective analysis of the true benefits and variation in results. Second, we need comparisons of antidepressants with other treatments and combinations of treatment. One study, published since the meta-analysis by Tomkins et al was written, meets these criteria: Holroyd et al compared TCAs with stress management treatment and placebo in 233 patients with tension headaches (almost twice the size of the largest trial in this meta-analysis). 38% of patients benefited from TCAs (less than in the current analysis), whereas combined treatment benefited 64% of patients.3

Conclusion
In patients with chronic headache, treatment with antidepressants is associated with overall improvement in headache and improvement in headache burden.

Antidepressants v placebo for chronic headache

COMMENTARY
The meta-analysis by Tomkins et al concludes that 1 in 3 patients with chronic headaches benefits from antidepressants. The effect is independent of headache type (migraine or tension) and drug class (TCAs, serotonin receptor antagonists, or SSRIs), with the possible exception that SSRIs are not as well studied and may be less effective. The effect seems independent of the presence of depression, but studies are inconsistent.
