Advances in evidence-based information resources for clinical practice

The health sciences literature contains the most current and detailed accounts of the testing of various phenomena and innovations related to health promotion and disease control. It also contains the best information available for the management of many healthcare problems. It is voluminous, however, and is often neither well written nor organised for easy clinical application. As a result, its use for solving clinical problems is challenging for even the most persistent and knowledgeable clinicians. Most clinicians indicate that they feel overwhelmed by the literature and don’t attempt to use it for solving clinical problems.

Clinicians can use the clinical literature to support clinical decisions in 2 complementary ways: for regular surveillance and for problem oriented searches. Both methods require an appreciation of the many purposes of the clinical literature. They also require a basic understanding of the strengths and weaknesses of studies for providing information that is valid and clinically applicable for questions related to the cause, course, diagnosis, and treatment or prevention of health problems.

In general, the peer reviewed journal literature serves science rather than clinical practice, with its prime function being to facilitate communication from scientist to scientist. Most of the investigations reported in journals are non-definitive tests of hypotheses and innovations, only a small portion of which may eventually survive testing well enough to warrant routine clinical application.

Reports of definitive studies (scientist-to-clinician communication) are not frequently seen. This situation is cause for both celebration and dismay: celebration because clinicians need to review only a small portion of the literature, and dismay because journals scatter definitive studies among many preliminary investigations. The reader must know and apply critical appraisal skills to identify them.

Clinical review articles are published even less frequently than definitive studies. These reviews constitute clinician-to-clinician communication and the new standards for doing and reporting systematic reviews enhance the likelihood that they will provide valid conclusions based on the best available evidence. Unfortunately, audits of the methodological rigour of review articles published in journals over the past few years show that many poor quality reviews are still being published in journals. This problem highlights the need for clinicians to have some knowledge of the principles of critical appraisal.

Many journals also publish case reports and case series. Although at first these seem classifiable as clinician-to-clinician communication, they are perhaps best classifiable as clinician-to-scientist communication. They present ideas that are based on careful observations of unplanned events and that need to be tested in future, planned investigations.

Finally, clinical journals also publish non-clinical scientific articles on a wide range of topics, including news, ethics, parables, and letters. These articles leaven the literature and add enjoyment but at a cost if they distract attention from definitive studies or mislead readers into thinking they bear definitive news for clinical practice when they do not.

Problem oriented searching of the clinical literature

The most potent stimuli to learning in clinical practice are the clinical problems we encounter when caring for our patients. To use the clinical literature to help us address these problems, we need to know how to search that literature effectively and efficiently. Recent EBM Notes in Evidence-Based Medicine have described both existing resources and search techniques to help clinicians gain quick, easy access to the evidence needed for specific patient questions. These include finding the systematic reviews, evidence-based summaries, and original scientist-to-clinician reports relevant to patient care. Although there is no single complete solution, existing resources are improving and new ones being developed that we wish to keep readers abreast of (appendix).

A new addition to this journal

Growth of evidence resources has exploded over the past few years, and it is now becoming a challenge for clinicians to find the most valid and useful evidence-based resources with which to practice. Beginning with this issue, a section titled “Resource Corner” will publish reviews of evidence-based healthcare resources written by frontline clinicians. These resources will include journals (primary and secondary), evidence-based textbooks, computer software, and web sites. Each issue of the journal will contain up to 2 reviews of such products.

Only clinicians without competing interests in the resource under review will be asked to write a review. Our reviewers will be asked to consider specific methodological guides (available to view on http://hiru.mcmaster.ca) when assessing these resource products. In particular, they will consider whether the authors of the resources have identified explicit criteria for determining the validity of the evidence and whether they adhere to these criteria. The reviewers will also provide a “bottom line” recommendation indicating whether and how the resource could be used in practice. We will make the reviews available on the web and will provide electronic links to the reviewed product where possible.

If you would like to review an evidence-based healthcare resource for this journal or would like to nominate a product to be reviewed, please contact us (Dr Sharon Straus, Department of Medicine, Mount Sinai Hospital, Toronto, Ontario M5G 1X5, Canada; Fax +1 416 586 8434).
