Long acting nifedipine was as effective as hydrochlorothiazide plus amiloride for reducing mortality and morbidity in hypertension

QUESTION: In patients with hypertension who are at high risk for cardiovascular (CV) events, is long acting nifedipine, a calcium channel blocker, as effective as co-amilozide (hydrochlorothiazide and amiloride) for preventing CV and cerebrovascular mortality and morbidity?

Design
Randomised (allocation concealed*), blinded (patients, physicians, and outcome assessors),* placebo controlled trial with ≥ 3 years follow up (Intervention as a Goal in Hypertension Treatment [INSIGHT] trial).

Setting
703 centres in 8 countries in western Europe and Israel.

Patients
7343 patients with hypertension were enrolled, 6575 were randomised, and 6321 (mean age 65 y, 54% women) were studied after exclusion of 9 centres because of protocol violations. Patients were required to have ≥ 1 additional CV risk factor (hypercholesterolaemia, smoking, family history of early myocardial infarction [MI], left ventricular hypertrophy or strain, coronary artery disease, or peripheral vascular disease). Follow up was 94%.

Intervention
3157 patients were analysed in the long acting nifedipine group (30 mg/d), and 3164 were in the co-amilozide group (hydrochlorothiazide, 25 mg/d, and amiloride, 2.5 mg/d). If hypertension persisted, the regimen was intensified in steps that included doubling the dose of the study drug; doubling the dose of the second drug; and adding another antihypertensive drug other than a calcium channel blocker or diuretic.

Main outcome measures
A composite end point of CV or cerebrovascular death and non-fatal MI, stroke, and heart failure. Secondary outcomes were all cause mortality, vascular death, and non-fatal vascular events.

Main results
Blood pressure (BP) decreased in both groups to approximately 138/82 mm Hg. Non-fatal heart failure was more common in the nifedipine group than in the co-amilozide group (0.8% v 0.3%, p = 0.028) as were fatal MI (0.5% v 0.2%, p = 0.017) and all adverse events (49% v 42%, p < 0.001). Withdrawals because of adverse effects were higher in the nifedipine group than in the co-amilozide group (25% v 16%, p < 0.001). The groups did not differ for the primary outcomes, including the composite end point (6.5% in the nifedipine group v 5.8% in the co-amilozide group, p = 0.35), all cause (p = 0.95) or cause specific mortality (p ≥ 0.14), non-fatal MI (p = 0.52), sudden death (p = 0.43), stroke (p ≥ 0.52), fatal heart failure (p = 0.63), or non-fatal CV events (p ≥ 0.1).

Conclusions
Nifedipine and co-amilozide were equally effective for preventing cardiovascular and cerebrovascular mortality and morbidity in high risk patients with hypertension. Fewer patients, however, tolerated nifedipine.

COMMENTARY
INSIGHT and NORDIL add to the acronymic litany of recent trials addressing pharmacotherapy of hypertension—this litany consists of multiple trials with multiple comparisons spawned by multiple drugs from multiple classes with multiple actions. With the addition of the INSIGHT trial and NORDIL study, we have 10 completed long term trials that compare calcium antagonists with other antihypertensive drugs.

Such trials that evaluate morbidity and mortality effects of calcium antagonists have variable findings that are difficult to interpret:

- None was large enough to reliably detect moderate differences (10% to 15%) in such clinically important outcomes as MI.
- BP control with monotherapy was not achieved in as many as one third to one half of trial participants, depending on baseline and target BP concentrations.
- Comparisons among agents were usually complicated by the addition of second and third drugs.
- In large trials, such as INSIGHT and the Swedish Trial in Old Patients (STOP-2), a third or more of the participants were withdrawn from their initially assigned regimens because of adverse effects, difficulty with adherence to long term treatment, or both.
- Occasional findings within trials, such as more fatal MI and non-fatal heart failure with calcium antagonists in the INSIGHT trial and fewer strokes with calcium antagonists in the NORDIL study, may result from chance because several comparisons were usually done.
- Intermediate and long acting non-dihydropyridine and dihydropyridine calcium antagonists were being evaluated. Clinicians are rightfully wary of generalising beneficial and harmful class effects across these agents.

QUESTION: In middle aged patients with hypertension, is diltiazem, a non-dihydropyridine calcium antagonist, as effective as diuretics, β blockers, or both at preventing cardiovascular (CV) events?

### Design
Randomised (allocation concealed*), blinded (outcome assessors),* controlled trial with mean follow up of 4.5 years (Nordic Diltiazem [NORDIL] study).

### Setting
1032 primary healthcare centres in Norway and Sweden.

### Patients
10,881 patients (mean age 60 y, 51% women) who had hypertension (diastolic blood pressure [BP] ≥100 mm Hg on 2 occasions) and were aged 50 to 69 years (extended to 74 y during the study). Follow up was >99%.

### Intervention
Patients were allocated to diltiazem (n = 5410) or to diuretics or β blockers, or both (n = 5471). If hypertension persisted, the regimen was intensified. Diltiazem was started at 180 to 360 mg/day, with stepped addition of the other drug, an ACE inhibitor or thiazide diuretic or β blocker, and any other antihypertensive drug. In the other group, a thiazide diuretic or β blocker was started with stepped addition of the other drug, an ACE inhibitor or β blocker, and any other antihypertensive drug except a calcium antagonist.

### Main outcome measures
BP and combined fatal and non-fatal stroke, fatal and non-fatal myocardial infarction (MI), and other CV death.

### Main results
Mean BP decreased in both groups, to 155/89 in the diltiazem group and to 152/89 mm Hg in the diuretics and β blocker group. For patients who remained in the study for ≥24 months, decreases in systolic but not diastolic BP were smaller in the diltiazem group than in the diuretics and β blocker group (20/19 v 25/19 mm Hg, p < 0.001). The groups did not differ for the combined primary end point (16.6 v 16.2 events/1000 patient years, p = 0.97), all MI (7.4 v 6.5, p = 0.17), CV death (5.2 v 4.5, p = 0.41), all cause mortality (9.2 v 9.0, p = 0.99), all cardiac events (20.2 v 19.2, p = 0.57), diabetes mellitus (9.4 v 10.8, p = 0.14), and congestive heart failure (2.5 v 2.1, p = 0.42). Patients in the diltiazem group had fewer strokes than patients in the diuretics and β blocker group (6.4 v 7.9 events/1000 patient years, p = 0.04). The rate of adverse effects was similar among the groups.

### Conclusion
Diltiazem was as effective as diuretics, β blockers, or both for preventing the combined end point of stroke, myocardial infarction, and other cardiovascular death.

### Commentary—continued from previous page
- Calcium antagonists are being compared with different agents within different classes. Clinicians realise that simple conclusions about calcium antagonists compared with "all other" agents are unlikely
- Some trials, such as NORDIL, do not achieve equivalence in BP lowering among calcium antagonists and other agents.

Given these complexities, we clinicians can embrace the following "truths." We have no strong, consistent evidence that intermediate or long acting calcium antagonists are superior or inferior to other antihypertensive agents in reducing CV disease and mortality. We have suggestive worrisome evidence that some intermediate and long acting calcium antagonists may increase such cardiac harms as MI and heart failure more than do diuretics (INSIGHT trial) or ACE inhibitors.*+ We know that adverse effects of antihypertensive treatments vary. For example, peripheral edema is reported by as many as 25% of people taking calcium antagonists (INSIGHT trial), and cough is reported by as many as 30% of those taking ACE inhibitors.6 We know calcium antagonists are often more expensive than other anti-hypertensive agents. While we await results of additional large, long term trials, many evidence-based clinicians will continue to choose agents other than calcium antagonists as first-line treatment for patients with hypertension.
